FOREWORD

This report, Bulletin 69-63, is the first of an annual series on the subject of high water in California.

This report was prepared, and it will be the purpose of subsequent reports of this series, to provide (in one report) information on precipitation, and peak flows and stages, resulting from the major storms of the water year. These reports will contain a summary of the water year events, a description of the general weather characteristics preceding and during the storm period, a discussion of the precipitation characteristics, a discussion of the resulting runoff, and a review of the flood damage. Tabulations of precipitation comparisons, peak flows and stages, and reservoir storage data are included in the appendixes.

Basic data for this report was supplied by many governmental and private agencies. Among these were the United States Weather Bureau, United States Geological Survey, United States Bureau of Reclamation, Corps of Engineers, Pacific Gas and Electric Company, East Bay Municipal Utility District, and numerous other public and private districts and agencies.

The data appearing in this report are considered to be quite accurate and reliable. It should be noted, however, that hydrologic data may be revised (usually the changes are minor) at a later date on the basis of subsequent studies and information. Therefore, all data should be considered to be preliminary and subject to revision.

THE RESOURCES AGENCY OF CALIFORNIA
DEPARTMENT OF WATER RESOURCES
1120 N. STREET, SACRAMENTO

May 13, 1964

Honorable Edmund G. Brown, Governor
and Members of the Legislature of
the State of California

Gentlemen:

I have the honor to transmit herewith Bulletin No. 69-63, entitled "California High Water, 1962-1963." This report contains a summary of the 1963 water year events. It includes information on precipitation, peak flows and stages, and flood damage resulting from the major storms of the water year. The report is for the information of governmental and private agencies, and the public.

This is intended as the first of an annual series.

Sincerely yours,

William E. Warne

CALIFORNIA HIGH WATER

1962 - 1963

SUMMARY

It seems quite appropriate that this new series of reports should begin in a year of relatively high water and unusual hydrologic and meteorologic phenomenon. The 1962-63 water year qualified completely in this respect and was characterized by alternating periods of flood and potential drought.

The water year begins October 1. About this time of year, Californians expect to see the first fall showers -- which mark the end of the hot, dry summer and the beginning of the precipitation season. In 1962, the showers began on October 11, and for the portion of the State which they hit, it was more of a deluge. From October 11 through 13, rainfall of record-shattering intensity pelted a strip about 100 miles wide. This belt of heaviest concentration extended from the San Francisco Bay area northeastward through the basins of the Feather and Yuba Rivers in the Sierra Nevada. Many stations in these watersheds received more than 800 percent of their average October precipitation from this storm.

The unusual October storm was followed by record-breaking fog which covered most of the floor of the Central Valley during 54 days of the subsequent four-month period. However, during the end of November and in early December, another severe Pacific storm did hit the State of Oregon with the southern extremities of this storm causing heavy rainfall in the North Coastal area. Generally speaking, the highest flows of the season for this

area were recorded on streams of the Klamath Basin and northward. Except for the North Coastal area, the months of November, December, and most of January, were alarmingly dry and set new records for consecutive days without rain (for that time of year). This dry period was brought to a violent end in late January by another storm of flood-producing intensity. This storm, in itself, was quite unusual; it was an extremely warm type with precipitation falling as rain as high as 9,000 feet. There was negligible snowpack at the time and the large amounts of precipitation falling on bare or frozen ground brought immediate and dramatic results. Streamflow on all Central Valley streams was high, and the peak flow on the Yuba River at Narrows Dam exceeded the all-time record. This January-February storm was quite general with heavy runoff in all but the southern portion of the State.

By mid-March it had indeed been an unusual season -- essentially dry, but punctuated by two violent, flood-producing storms. Nature continued on in her own unpredictable way. It began to rain and snow in mid-March and precipitation fell in light to moderate amounts almost daily through April in all but the southeast desert region. These were the storms that everyone wanted and California needed. Resultant streamflow was good, but not dangerous, and generally adequate water supplies for the season were assured.

Meteorology of the October 1962 Storm

Early-season rain storms have occurred in September and October in the past, but the October 1962 storm set new records for intense and concentrated rainfall. The weather map on October 9th showed a front, oriented WSW-ENE across the extreme northern part of California. This front intensified and moved southward on the following day to a stationary position along the line San Francisco-Sacramento. To the south of the front and above the sloping frontal surface, strong southwesterly winds aloft brought a warm, moist air mass which produced heavy rains due to both orographic and frontal lifting.

On this front there were two occluding frontal waves which gave substantial precipitation amounts in Northern and Central California. These waves passed, in sequence, through California in the afternoon of October 11th and in the evening of October 12th (Columbus Day).

The first wave developed near 40°N 150°W (1200 miles WNW of San Francisco) about 0400 PST on October 10th. The wave occluded rapidly eastward from its point of genesis until its passage as an occluded front through Northern California in the afternoon of October 11th. The second wave of the October storm originated as a perturbation on the polar front by the typhoon FREDA which was filling and becoming an extratropical low pressure center.* This wave, formed by FREDA, appeared west of the international date line in the Pacific Ocean on October 5th. The wave moved northeastward

*Typhoons or hurricanes, on moving into mid-latitudes, usually draw fronts into their circulations and then assume characteristics of an extratropical low pressure center (the conventional mid-latitude storm with their warm and cold fronts).

from its inception point for several days, then curved to move towards the southeast. Finally, before reaching the California coast during the afternoon of October 12th, the main LOW center recurved to move towards the northeast along the Oregon coast. Associated with this LOW was a very strong pressure gradient which resulted in strong winds; these winds of almost tornado intensity blew down large quantities of timber in Northern California and, especially extensively, in Oregon.

During the period of these two occluding waves, the freezing level over the central Sierra remained at 10,000 feet through the evening of October 12th when it lowered to 8,000 feet. Although the storm of October 12th involved an old typhoon with strong winds, the air mass was not unusually warm; the upper air temperatures did not exceed the high values experienced in the December 1955 storm. In the final phases of the October storm, when the front pushed southward into the San Joaquin Valley on the morning of October 14th, the freezing level lowered in the Sierra to 5,000 feet.

The normal storm track for October in the North Pacific originates at 40° to 45°N near the date line and extends ENE and NE into the Gulf of Alaska. The October 1962 storm track was well to the south of this normal track -- about 15 degrees of latitude.

Another important feature of this October storm was that the frontal zone, along which the waves moved, remained almost stationary across Northern California. The orientation of the front was approximately SW-NE during the period before and after the first wave moved through California. The second wave, moving across California as an occluded front, had an

orientation NNE-SSW, and this front moved south of the Sacramento-Oakland line on the evening of October 12th. However, the front moved northward within six hours. Thus, the nearly stationary position of the front kept the rainfall continuous over a band about 100 miles wide across Northern California.

Mass rainfall curves for a number of stations are shown on Plates Nos. 6 to 11. The period covered by the mass curves extends from October 7th through October 14th. The onset of rains in the northern part of the State appeared earlier due to the weather front which was located over that area. At many stations the lull or decrease of the rate of rainfall between the waves of October 11th and October 12th can be seen by the change in slope of the curves. At other stations, notably in the Sierra, there is little or no break in the slope of the curves. Many of the recording rain gages experienced mechanical difficulties, or overflow of the collecting cans, so that detailed data is missing in the heavy rainfall areas. The rate of rainfall associated with the wave of October 12th was very intense, and the radar observations gave the strongest echoes that have been experienced by the WSR-57 (STORMFINDER) radar at Sacramento since its installation in 1960.

A general isohyetal map of the northern and central portion of the State for the October storm is shown on Plate No. 2. This map shows the heavy rainfall area to lie in a 100-mile wide swath through the San Francisco Bay Area and the Feather-Yuba River Basins. Storm amounts include 15 inches in the East Bay Area, 20 inches in the Santa Cruz Mountains, and 25 inches in the Feather and Yuba River Basins. A more detailed isohyetal map for the Feather-Yuba-Bear-American River Basins is shown on Plate No. 3. Rainfall amounts tapered off sharply south of Sacramento in the Central Valley and south of the American River Basin in the Sierra Nevada.

The following table lists the maximum 1, 6, and 12 hourly rainfall amounts at representative stations:

TABLE I

MAXIMUM RATES OF RAINFALL IN THE OCTOBER STORM

Area	Station	Maximum Rainfall

* USFS recording rain gage data through 2300, October 11th; subsequent data from DWR radio rain gage supplemented by radar observations.

A comparison of 1-, 2-, 3-, and 4-day rainfall amounts at selected stations during this storm with other major storms is given in Table A-1 in Appendix A.

Meteorology of the January-February 1963 Storm

During most of January 1963 the mid-tropospheric flow pattern consisted of a large ridge of high pressure near 135°W longitude (700 miles west of San Francisco) and a deep trough of low pressure over the United States east of the Great Basin. This flow pattern prevailed until the last three days of the month, and accounted for the pronounced outbreaks of cold, arctic air during January over the most of the United States, even into California. On January 28, the ridge of high pressure weakened at mid-latitudes to permit a Pacific storm system to finally break into California. The first storm system consisted of an occluded front which moved inland over California on the morning of January 30. Rain in advance of this front, however, began earlier on the evening of January 29. The trailing end of this front extended into the eastern Pacific Ocean in the latitude band 25° to 30°N. A broad area of low pressure to the north of this front remained as a feature of the weather map for the next few days. A new wave development on the trailing front occurred on January 30, grew in size and intensity, and moved eastward toward the California Coast on the morning of January 31. This second system was more intense than the first and brought heavier rains to Northern and Central California. The occluded front of this storm moved inland in the North Coast area about 1000 PST on January 31 and 24 hours later was located in Utah with the trailing end of the front crossing the northern San Joaquin Valley. On February 1 this portion of the front weakened as pressures began to rise over California. Further storm developments in the Pacific were forced to take a more northerly track into Oregon, Washington, and British Columbia.

The storms of January 29-February 1 were warm rainstorms with the freezing level in the central Sierra Nevada near the 5,000-foot level on January 29 and rising to 9,000 feet on January 31 when the heavier rain fell. This factor made the runoff contribution from the mountains high. There was no snow on the ground below elevation 7,000 feet, and the ground in the mid-elevation range (5,000-7,000 feet) was largely frozen.

Mass rainfall curves for key stations in various sections in Northern and Central California are shown on Plates Nos. 12 to 17. The onset of rains from the first occluded front occurs at most stations in the afternoon and evening of January 29. There was some tapering off of the rate of rainfall between this and the second system in all areas except at stations in the Sierra. The rainfall associated with the second front can be seen from the steepness of the mass curves on January 31. Some of the maximum rates of rainfall observed in this storm are given in the table on the following page.

The areal distribution of the storm precipitation is shown on the isohyetal map of Plate No. 4. The areas of maximum amount include the Clear Lake area with 15 inches, the Santa Cruz and Santa Lucia Mountains with 20 inches, the Sierra Nevada with 20 inches extending from the Feather River Basin in the north to the Kings River Basin in the south. A more detailed isohyetal map for the Feather-Yuba-Bear-American River Basins is shown on Plate No. 5. The heavy rainfall in the Yuba and American River Basins resulted in new record peak inflows at Harry L. Englebright (Narrows) and Folsom Reservoirs.

A comparison of rainfall amounts for 1, 2, 3, and 4 days at selected stations in this storm (January 29-February 3) with other major

storms is given in Table A-1 of Appendix A. New record amounts were set at a number of stations. These are indicated in the table with an asterisk.

TABLE II

MAXIMUM RATES OF RAINFALL IN THE JANUARY-FEBRUARY STORM

Area	Station	Maximum Rainfall		
		1 Hour	6 Hours	12 Hours
North Coast	Miranda Spengler Rch	.39	1.98	3.01

	Sierraville RS	.31	1.61	2.84
	Portola	.20	.83	1.62
	Oroville RS	.21	.91	1.49
American River Basin	Blue Canyon WB AP	.56	2.97	5.50
	Soda Springs 1E	.63	2.78	5.45
	Georgetown	.55	2.54	3.92
	Mt. Danaher	.40	1.70	3.25

The antecedent soil moisture at the beginning of the storm was moderately wet. The last significant rainfall over Northern and Central California had occurred on December 18. The city office of the U. S. Weather Bureau in Sacramento had a period of 41 days without rain, the second longest period on record without rain for the mid-winter months. Nevertheless, some moisture was still contained in the soils from the early October storm and the December storms. The intensity of rains in the January-February storm rapidly fulfilled the remaining soil moisture deficiency, so that runoff increased significantly. Also, at elevations below 7,000 feet in the mountains, frozen bare ground served to minimize infiltration losses. For the Feather River Basin above Oroville (drainage area 3,611 square miles), the overall runoff factor for the storm was about 37 percent in contrast to the 18 percent in the October 1962 storm.

Runoff

Much of California north of the Tehachapi Mountains experienced periods of high flood flows on many of its streams during the year 1962-1963. Following is a brief discussion of each basin in California where moderate to high runoff occurred.

North Coastal Area

The October Storm in the North Coastal Area produced low peak flows in the Smith, Klamath, Trinity, and Eel River Basins. Further south in the Russian River Basin the peak flows were in the low to moderate range. The hydrograph of the Russian River and Coyote Reservoir Operations, shown on Plate No. 18, gives an example of the Russian River Basin.

The Russian River near Guerneville peaked at 30,800 cfs, compared to 63,100 cfs in 1960, and the maximum recorded peak of 90,100 cfs in 1955.

The November-December Storm centered in Oregon with the southernmost portion of the storm causing the highest peak flows for the season in the Smith, Klamath, and Mad River Basins. The Smith River at Crescent City had a peak stage of 113,000 cfs, as compared to 74,300 cfs in 1960, and the maximum recorded peak in 1955 of 165,000 cfs. The Klamath River at Somesbar had a peak flow of 85,300 cfs, as compared to 70,700 cfs in 1960, and the maximum recorded peak flow of 202,000 cfs in 1955. The Klamath River at Klamath had a peak flow of 176,000 cfs, as compared to 194,900 cfs in 1960, and the maximum recorded peak flow of 425,000 cfs in 1955. The Mad River near Arcata had a peak flow of 28,900 cfs, as compared to 48,000 cfs in 1960, and the maximum recorded peak of 77,800 cfs in 1955. The

recorded flows south of the Mad River Basin for this storm fall within the range of low flood flows.

The hydrographs of the Smith, Klamath, and Trinity Rivers, shown on Plates Nos. 26 and 27, illustrate the flows in the northern basins of the North Coastal Area.

The January-February Storm caused low to moderate peak flows in the northerly basins and high peak flows in the central and southerly basins.

The hydrographs of the Smith, Trinity, Klamath, Eel, and Russian Rivers, and Trinity Reservoir Operation, shown on Plates Nos. 28, 29, 30, and 31, are typical examples of the flood flows of this storm for the North Coastal Area.

The Eel River at Scotia had a peak flow of 252,000 cfs, as compared to 343,000 cfs in 1960, and the maximum recorded peak of 541,000 cfs in 1955. The Russian River near Guerneville had a peak flow of 71,800 cfs, as compared to 63,100 cfs in 1960, and the maximum recorded flow of 90,100 cfs in 1955. There was one new peak flow of record at Dry Creek near Cloverdale, tributary to the Russian River, of 17,700 cfs, bettering the peak of 17,600 cfs recorded at this station in 1955.

San Francisco Bay Area

The October Storm resulted in high flood flows in the East Bay Area. The southerly and northerly portions of this area had generally low to moderate flood flows, with very low flows in the streams of the Livermore- Pleasanton Area.

The hydrographs of Walnut and San Lorenzo Creeks, shown on Plates Nos. 19 and 20, are examples of high flood flows in the East Bay Area; and

hydrographs of the Napa River and Alameda Creek (also shown on Plates Nos. 19 and 20), illustrate the moderate and low flows of the northerly and southerly portions, respectively.

The Napa River near Napa peaked at 6,580 cfs, as compared to the maximum recorded peak flow of 12,300 cfs in 1960. Two maximum peak flows of record were established in the East Bay Area. San Ramon Creek at San Ramon crested at 1,600 cfs, as compared to 1,490 cfs recorded in 1958, and San Lorenzo Creek at Hayward peaked at 7,460 cfs well over the peak flow of 5,100 cfs recorded in 1958. In the southerly portion, one moderate peak flow of 6,700 cfs was recorded on the Guadalupe River at San Jose, as compared to the maximum recorded peak flow of 9,150 cfs in 1958.

January-February Storm - The runoff for this area can be classified as moderate to high flood flows. In the North Bay Area, the Napa River near Napa had a maximum peak flow of record of 19,000 cfs, surpassing the previous peak of 12,300 cfs in 1960. Redwood Creek near Napa, tributary to the Napa River, had a maximum peak flow of record of 1,350 cfs, as compared to 1,070 cfs in 1960.

The East Bay Area had a record peak flow on San Ramon Creek at Walnut Creek of 8,110 cfs, as compared to the previous peak flow of 6,890 cfs recorded in 1955.

In the southern portion of this area, Arroyo Valle at Pleasanton had a peak flow of 8,000 cfs, as compared to the maximum peak flow of record of 11,300 cfs in 1958. Alameda Creek at Union City peaked at 1,750 cfs, in contrast to the maximum recorded peak flow of 260 cfs in 1960. Patterson Creek at Union City crested at 10,700 cfs, as compared to the

previous maximum peak flow of 3,700 cfs in 1959. However, the three stream gaging stations mentioned above have only been in operation since 1958.

Central Coastal Area

October Storm - The streams in the Santa Cruz Area and westerly portion of the area between Big Sur and San Simeon adjacent to the coast, had low peak flows during the October storm. The remainder of the basins in the Central Coastal Area had no peak flows with the exception of Arroyo Seco Creek in the Salinas River Basin, which experienced a low peak flow.

A hydrograph of the San Lorenzo River, shown on Plate No. 20, is an example of the low flows occurring in the Central Coastal Area during the October storm. The San Lorenzo River at Big Trees had a peak flow of 7,410 cfs, in contrast to the maximum peak flow recorded in 1955 of 30,400 cfs. The Nacimiento River near Bryson, located just upstream from Nacimiento Reservoir, had a peak flow of 2,740 cfs, as compared to the maximum peak flow of record of 30,300 cfs in 1955.

January-February Storm - Peak flows in the streams of this area varied from low to high. The northerly basins experienced mostly moderate peak flows, with the mountain region west of the Salinas River Basin having high peak flows and the remainder of the basins having peak flows in the low range.

The hydrographs, shown on Plates Nos. 33 and 34, depict the variety of flows in the Central Coastal Area. In the north, the San Lorenzo River at Big Trees peaked at 13,000 cfs, as compared to the maximum recorded peak of 30,400 cfs in 1955, and the Pajaro River at Chittenden peaked at 11,400 cfs, in contrast to the maximum recorded peak in 1955 of

24,000 cfs. In the westerly portion of the central region, the Nacimiento River near Bryson had a peak of 22,700 cfs, as compared to the maximum recorded peak in 1955 of 30,300 cfs. The Salinas River, sometimes referred to as the upside-down river, had a peak of 12,400 cfs near Bradley, and downstream at Spreckels had a peak of 7,840 cfs, as compared to the maximum recorded peak in 1958 of 28,400 cfs, and in 1938 of 75,000 cfs, respectively.

Central Valley Area

The October Storm runoff produced moderate to high peak flood flows in the major basins north of the Cosumnes River. The southerly portion of the Central Valley Area experienced either low or no October peak flows. Hydrographs and reservoir operations on Plates Nos. 21, 22, and 23, illustrate the flows from the major basins in the Sacramento Valley. Plots of the gage heights on the Sacramento and tributary river systems are shown on Plates Nos. 24 and 25.

In the northerly area of the Central Valley, Shasta Dam had a peak inflow of approximately 65,000 cfs. The majority of the runoff inflow volume of this storm was impounded in Shasta Reservoir increasing the storage over 300,000 acre-feet. The maximum peak discharge return to the Sacramento River at Keswick Dam was 9,000 cfs. This low flow combined with the low flows from the west side and high flows from the east side produced a peak flow of 68,800 cfs at Ord Ferry, well within the general flood control objective of 130,000 cfs at the upper end of the Sacramento River Flood Control Project. An example of flood flows on the east side was a peak flow of 24,800 cfs on Cow Creek near Millville, as compared to the maximum peak of record of 45,200 cfs in 1951. On the west side Cottonwood

Creek near Cottonwood had a peak flow of 6,500 cfs, as compared to the maximum peak flow of record of 52,300 cfs in 1941. Stony Creek near Hamilton City had a peak flow of 1,040 cfs, in contrast to the maximum peak flow of record of 39,900 cfs in 1958.

Further south on the east side, the Feather and Yuba River Basins had high peak flood flows. Three streams in this area had new peak flows of record. They were: Spanish Creek tributary to the North Fork Feather River, South Honcut Creek tributary to the Feather River, and Deer Creek tributary to the Yuba River. The Feather River at Oroville had a peak flow of 136,000 cfs, as compared to the maximum observed peak in 1907 of 230,000 cfs (stage from high water mark), and the Yuba River at Englebright Dam had a peak flow of 91,000 cfs, as compared to the maximum recorded peak flow of 148,000 cfs in 1955. In the American River Basin, Folsom Dam had a peak inflow of 89,945 cfs. During the storm period 200,000 acre-feet of flood water was stored in the reservoir with a peak discharge to the American River at Nimbus Afterbay Dam of 5,000 cfs.

The remaining significant inflow to the Sacramento River Flood Control Project on the west side was Cache Creek at Yolo with 8,210 cfs, as compared to the maximum recorded peak of 41,400 cfs in 1958. Lake Berryessa on Putah Creek had a peak inflow of approximately 45,000 cfs. The very low maximum discharge of 53 cfs to Putah Creek from the reservoir resulted in an increase in storage of over 75,000 acre-feet.

The peak flood flow of the project at the latitude of Sacramento was about 201,500 cfs. The total volume of flow past this location for the month of October approximated 2,394,000 acre-feet.

In the Sacramento River Flood Control Project, overflow occurred at Colusa, Tisdale, and Fremont Weirs. The overflows were as follows:

TABLE III

Sacramento River Flood Control Project
WEIR OVERFLOWS

OCTOBER STORM

Weir	Beginning of Overflow		Length of Overflow Period	Peak Stage and Discharge
	Date	Time		
Moulton				No Flow
Colusa	10/13/62	0900	57 Hours	64.85 ft. 19,500 cfs
Tisdale	10/13/62	1400	105 Hours	48.30 ft. 11,000 cfs
Fremont	10/13/62	2300	192 Hours	38.34 ft. 159,000 cfs
Sacramento				No gates opened

The January-February Storm runoff in the Central Valley Area ranged from moderate to extremely high to record shattering. Reservoir operations and hydrographs on Plates Nos. 35 to 44 show the flows from the major basins in the Central Valley Area.

Plots of the gage heights on the Sacramento and tributary river systems are shown on Plates Nos. 45 and 46.

In the north, Shasta Dam had a peak inflow of 72,000 cfs from the Sacramento River, McCloud River, Squaw Creek, and the Pit River. The majority of the storm inflow was contained in Shasta Reservoir with a gain in storage of about 383,000 acre-feet. Keswick Afterbay Dam, regulator of Shasta discharges to the Sacramento River, had a peak discharge of

11,700 cfs. Downstream from Keswick on the west side, Cottonwood Creek near Cottonwood had a moderately high peak flow of 23,100 cfs, and Stony Creek near Hamilton City had the moderate peak flow of 9,300 cfs. On the east side, Cow Creek near Millville had a peak flow of 16,800 cfs, as compared to the maximum peak of record of 45,200 cfs in 1951.

Further south on the west side, Cache Creek at Yolo had a peak flow of 24,000 cfs, as compared to the maximum recorded peak of 41,400 cfs in 1958. Putah Creek inflow to Lake Berryessa was 86,000 cfs, surpassing the maximum recorded peak inflow of 85,300 cfs in 1958. The discharge to Putah Creek was maintained at 10 cfs, thus again adding significantly to the storage of the reservoir -- this time by 195,000 acre-feet for the storm period.

The Feather, Yuba, and American River Basins had the record-breaking flood flows. In the Feather Basin, Spanish Creek above Blackhawk Creek at Keddie had a peak flow of 15,000 cfs, bettering the maximum recorded peak of 13,200 cfs in October 1962. The Middle Fork Feather River near Merrimac had a peak flow of 65,400 cfs, topping the maximum peak of record in 1955 of 62,000 cfs. The Feather River at Oroville peaked at 191,000 cfs, as compared to the 1955 peak of 203,000 cfs, and the maximum observed peak flow of 230,000 cfs in 1907 (stage from high water mark).

In the Yuba River Basin, the North Yuba River below Bullards Bar Dam peaked at a stage of 42.0 feet (discharge to be determined later), surpassing the previous maximum record stage of 39.0 feet (discharge of 70,000 cfs) in 1955. The Yuba River at Englebright Dam had a new maximum peak flow of record of 149,000 cfs, as compared to the previous maximum of record of 148,000 cfs in 1955.

In the American River Basin, tributary streams to the American River had several crest stages far surpassing previous record peak stages but discharges were not yet determined at the time of publication of this report. An example is the Rubicon River near Georgetown which crested at 25.6 feet, in contrast to the maximum record peak stage of 21.50 feet in 1955. The American's flood waters were second in volume only to the legendary flood of 1862. Folsom Dam had a peak inflow of 240,200 cfs, and during the storm stored approximately 370,000 acre-feet at the apex of the storm. This peak inflow surpassed the maximum peak flow in 1955 by 22,000 cfs. The peak discharge of Folsom Dam was 110,125 cfs which continued for 12 hours. This flow coupled with 69,000 cfs in the Sacramento River past Verona, required the opening of 45 of the 48 gates of the Sacramento Weir. The operation of the Sacramento Weir was smooth and efficient even though it was the first time the gates had been opened since 1955.

At the latitude of Sacramento, the peak flood flow was 289,700 cfs. The total volume of flow past this location for the month of February was about 4,556,000 acre-feet. The project passed the greatest peak flows in its history without a major levee break.

In the Sacramento River Flood Control Project overflow occurred at all the weirs and overflows were as follows:

TABLE IV

Sacramento River Flood Control Project
WEIR OVERFLOWS

JANUARY-FEBRUARY STORM

Weir	Beginning of Overflow		Length of Overflow Period	Peak Stage and Discharge	
	Date	Time			
Moulton	2/1/63	1640	41 Hours	79.33 ft.	6,600 cfs
Colusa	1/31/63	2150	117 Hours	66.09 ft.	35,800 cfs
Tisdale	2/1/63	0030	478 Hours	48.87 ft.	12,600 cfs
Fremont	2/1/63	0530	415 Hours	38.45 ft.	163,000 cfs
Sacramento	2/1/63	2038*	138 Hours**	31.83 ft.	85,000 cfs

*45 of 48 gates opened; operation completed at 2350, 2/1/63.
**Closure operations began at 1350, 2/5/63, and completed at 1435, 2/7/63.

Continuing down the east side of the Central Valley Area, the Cosumnes River Basin had extremely high peak flood flows. The Cosumnes River at Michigan Bar peaked at 39,400 cfs, second of record only to the maximum recorded peak flow in 1950 of 42,000 cfs. The remainder of the major basins on the east side from the Mokelumne River down to the Kern River had high peak flood flows. The reservoirs in these basins impounded the greater part of the rainfall-runoff before the waters reached the valley floor below. These basins had experienced several years of drought conditions and the charging of the reservoir capacity was welcomed by water conservationists.

Peak flows on the San Joaquin River and its tributaries were in the low range. This was due to the low storage status of the reservoirs in these basins and operation of these reservoirs to impound the majority of the storm runoff. An example of this situation was the San Joaquin near Vernalis which peaked at 12,400 cfs, in contrast to the maximum recorded peak flow in 1950 of 79,000 cfs.

April Storms - During this period a series of rainstorms and resultant runoff contributed greatly to reservoir storage facilities in the Central Valley. In the early spring, as previously stated, reservoir storage in the southern Sierra was quite low and it appeared that the area had the dismal prospect of a third consecutive year of drought conditions. However, the storms beginning in mid-March and continuing through April had the further advantage of a low freezing level. Significant snow deposition occurred down to relatively low elevations and immediate storm runoff was generally moderate. During the snowmelt runoff period most Central Valley reservoirs filled, with some spilling, thus completely reversing the earlier water supply outlook.

The storage at Shasta Reservoir increased approximately 1,000,000 acre-feet during this period. In early May the reservoir was full to capacity and the spillway flowed for the first time since 1958. On the west side, Lake Berryessa filled and the reservoir's gloryhole-type spillway flowed for the first time since completion of construction in 1958.

Folsom Reservoir filled to capacity in early June and the rest of the reservoirs on the east side of the Central Valley Area filled or greatly increased conservation storage. At the south end of the area, Isabella Reservoir in the Kern River Basin with a storage capacity of

570,000 acre-feet, filled to 370,000 acre-feet in June which was the highest recorded storage since its completion of construction in 1953.

The immediate runoff from the storms in April was of most significance on the Sacramento River. Moderate to high flood flows occurred during this period in the Sacramento River Flood Control Project.

In the middle of the month of April the highest discharge of the season of 45,000 cfs was released from Keswick Dam, afterbay of Shasta Dam. Subsequently, further down the Sacramento River, the gaging station at Ord Ferry recorded a flow of approximately 100,000 cfs. This flow was within the general flood control objective of 130,000 cfs at the upper end of the Sacramento River Flood Control Project.

Past the latitude of Sacramento the total volume of flow for the month of April was about 5,100,000 acre-feet.

All of the project weirs overflowed except the Sacramento Weir. The overflows were as follows:

TABLE V

Sacramento River Flood Control Project
WEIR OVERFLOWS

APRIL STORMS

Weir	Beginning of Overflow		Length of Overflow Period	Peak Stage and Discharge	
	Date	Time			
Moulton	4/12/63	1000	158 Hours	80.26 ft.	11,000 cfs
Colusa	4/7/63	1245	408 Hours	66.77 ft.	46,000 cfs
Tisdale	4/7/63	1330	424 Hours	48.72 ft.	11,800 cfs
Fremont	4/7/63	1600	487 Hours	36.56 ft.	68,000 cfs
Sacramento				No gates opened	

Lahontan Area

October Storm - The streams in the northern portion of this area generally experienced from low to high peak flood flows during the October storm. An example of high peak flows was the peak flow of 3,100 cfs on the Susan River at Susanville, as compared to the maximum record peak flow of 3,540 cfs in 1955. Further south, the Truckee River at Farad had a peak flow of 3,340 cfs, in contrast to the maximum record peak flow of 17,500 cfs in 1950.

January-February Storm - This storm produced high to extremely high peak flood flows on the streams in the northern portion of the Lahontan area. Two new maximum record stream peak flood flows were established in the Susanville area.

Willow Creek near Susanville had a peak flow of 816 cfs, surpassing the previous maximum peak flow in 1955 of 712 cfs, and the Susan River at Susanville peaked at 3,900 cfs, bettering the 1955 peak flow of 3,540 cfs. The Truckee River at Farad had a peak flow of 11,860 cfs, as compared to the maximum peak flow of 17,500 cfs in 1950.

Feather River at Hansels' Bridge in early March 1963 as a comparison to cover photo taken approximately the same location.

(Courtesy of Southern California Edison Co., photograph by Symons Flying Service)

The 33 applications requested a total of $908,659.74. Based upon an engineering field review of each application, the department recommended the amount of $661,836.52 as eligible for assistance under Public Law 875.

In the North Coastal Area high velocity winds felled more than a score of age old redwood trees across Highway 101 between Eureka and Crescent City temporarily closing the road. Heavy runoff caused damage to levees on Coffee and Swift Creeks in Trinity County. Excessive spilling from the reservoir damaged Ruth Dam's spillway chute, a property of Humboldt Bay Municipal Water District. The Van Duzen River at the Humboldt-Trinity county line changed course and eroded away approximately 25 acres of valley land.

In the Bay Area, damage to highways and roads was extensive. Alameda and Contra Costa counties caught the impact of the storm in this area. The heavy rainfall and resultant heavy runoff caused severe erosion and mud slides in and above the cities of San Leandro, Hayward, Berkeley, Oakland, Pleasanton, Walnut Creek, and Martinez. Debris from this erosion blocked water courses and culverts causing overflows which in turn resulted in damage to stream banks, levees, channels, storm drains, roads, culverts and other property.

The entire city of Oakland was isolated from the east as rain water flooded most main thoroughfares and closed the Broadway low-level tunnel into Contra Costa County. Oakland's Lake Merritt overflowed its banks and flooded adjacent streets.

Evacuation was the order of the day in many communities. Families were urged to vacate their homes in Linda Mar on the San Mateo County coast and in a low-lying section of San Bruno as flood waters began lapping at their doors. Low-lying areas in Marin County were under several feet of

water and Highway No. 1 northbound from Stinson Beach was closed as were several stretches of Highway No. 12.

Flooding in several locations in the city of Half Moon Bay caused damage to channels, and from silt and debris deposition. Flooding of the city's sewage treatment plant caused the plant to be inoperative. In the city of Pacifica, heavy storm water runoff caused deposition of silt and debris in channels and storm drains. Resultant flooding resulted in damage to the banks and channel lining on several streams in the area.

In the Central Valley Area, major rail lines and highways were closed. Numerous mud slides blocked the Western Pacific Railroad's Feather River route east of Oroville, delaying several passenger trains.

Sonora and Tioga passes were closed as were stretches of Highway 40-A beyond Oroville, Highway 99-W at Redding and Highway 99-E from Roseville to Wheatland.

In the north portion of the Central Valley Area, property damage was staggering and millions of dollars in crop damage were reported from agricultural areas. In Chico, the $10,000,000 rice crop, which must be harvested in dry weather, was under water. Beans and walnuts "worth a fortune" were also damaged by the rain, as were other major crops.

The North Fork Pit River flooded a large portion of Alturas causing a variety of damage to the community. High flood stage and velocities on Rattlesnake Creek damaged the Hot Spring Valley Irrigation works and facilities on this watercourse. The high stage of Ash and Dry Creeks inundated a significant portion of the town of Adin in Modoc County and damaged public facilities, principally two county bridges.

In Sierra County, heavy flow and resultant high velocities threatened the stability of the community water supply diversion dam located on Fletcher Creek, about 1/4 mile northwest of Calpine.

Occupants of two trailer courts and the whole town of Tobin, 40 miles northeast of Oroville on the North Fork of the Feather River, were evacuated after the torrential rains flooded the area. About 320 persons fled to safety. In the Oroville area hundreds of cattle were marooned and some were washed away into the river.

In the Sacramento River Flood Control Project, farmers in the bypass areas were alerted by the department that the weirs were forecast to overflow and inundate the bypass floodways. They were able to remove machinery, equipment and livestock from these floodways with time to spare.

In the Sacramento River Flood Control Project, damage to the system was of a minor nature. The more serious problems were encountered in Maintenance Area Nos. 3, 7, 8, and 13, and the upper end of Yankee Slough. A conduit separation within Maintenance Area No. 3 levee along the Feather River allowed levee material to be piped during high stage of this watercourse. An emergency sandbag dike and appropriate pipe repairs were made to remedy this condition.

Saturation and piping of levee material at three sections of a Maintenance Area No. 7 levee along the Feather River resulted in excessive slump displacement. Required material was replaced in the slumped areas to correct this condition.

Along the Yuba River approximately two miles of new levee in Maintenance Area No. 8 suffered slope erosion as a result of impinging

precipitation during the storm. Overtopping and resultant erosion occurred along a section of a Maintenance Area No. 13 levee along Cottonwood Creek. Employment of emergency measures was required to protect the levee and maintain travel on adjacent U. S. Highway 99-E during flood stage of the watercourse.

A high flood stage and debris accumulation at Brewer Road Bridge crossing of Yankee Slough in Reclamation District No. 1001 caused the right bank levee failure. Approximately one square mile of walnut orchards was inundated between Yankee Slough and Bear River Drive. The bridge was subsequently dynamited by U. S. Air Force personnel from Beale Air Force Base to remove the debris jam and allow flood waters to pass.

In the Sacramento River Delta, Little Holland Tract flooded about 6 a.m. on October 15; Prospect Island overflowed about 12 noon on October 15; and Liberty Island was inundated between 4 and 5 a.m. on October 16.

Mountain slides closed State Highway 89 along the west shore of Lake Tahoe and it remained closed until after the storm when repairs could be made.

January-February Storm

California, north of the Tehachapi Mountains, was hit hard by this storm. In Northern California hundreds of families were evacuated when swollen rivers menaced homes. Twenty-three major U. S. and California highways were closed by snow slides and floods. All major roads leading from Northern California to Nevada were closed. Also closed to travel were the Western Pacific and Southern Pacific Trans-Sierra Railroads.

Major disaster areas of this storm are shown on Plate No. 47. There were 12 applications requesting $929,280 in assistance under Public Law 875. The department investigated these applications for federal financial assistance relating to flood control, drainage and irrigation facilities and other works, in the disaster designated counties.

Based upon an engineering field review of each application, the department recommended the amount of $634,706 for assistance under Public Law 875. The above-mentioned total monies requested by public agencies and total monies approved by the department very closely approximate the October program.

In the North Coastal Area, excessive runoff and the consequent high stage and velocity of the Scott River resulted in damage to the Scott Valley Irrigation District's pumping plant diversion dam. The dam was overtopped and the right abutment and adjacent bank land was severely damaged. The district's pumping plant, farm lands, and a gravel plant downstream were seriously jeopardized by the high waters, and erosion established a new channel and washed away several acres of land immediately below the dam.

Excessive spilling from Ruth Dam Reservoir damaged the dam's spillway chute and training levee along the left bank of the chute section. Similar damage had occurred during the October storm.

The Eel River flooded over its banks and inundated large areas of the lower river valley in the vicinity of Loleta. Considerable land and farm buildings were inundated. The Eel also flowed across the state highway to Ferndale and closed off other roads in this vicinity for a short duration.

Many roads and highways were closed due to the storm in Mendocino and Sonoma counties and many communities had power outages and telephone service disruptions.

Flood-hardened veterans along the Russian River said this storm was worse than '58, but not nearly as severe as '55. The town of Guernevil was flooded on the fringes, inundating resort areas, homes, and business establishments. The lowlands of Geyserville were flooded, mostly in low orchards, but shallow flooding took place in parts of the residential section of the community.

In Healdsburg the troubles came from the west -- the Dry Creek runoff -- rather than the Russian River. The western portion of the city was flooded by Dry Creek. Also flooded were the Santa Rosa lowlands.

In Napa an estimated 200 families were evacuated from the downtown section when the Napa River spilled over its banks. Water poured through many homes and businesses in the area. Along the Napa River, water rose at Calistoga to within a foot of the 1955 flood level backing up sewage drains in some areas.

Further south in Santa Clara County, it was reported that flooding took place in or near the cities of Morgan Hill, Gilroy, Agness, and Alviso. In Alviso water was eight feet deep at points and a high tide on nearby San Francisco Bay threatened to increase the water level. This necessitated evacuating 100-150 people from the town. Several isolated cases of flooding in low-lying lands were observed along Highway 101 south of San Jose and many roads and highways were closed during the storm. The storm caused severe damage to the banks and levees of various streams and channels in Santa Clara County. It also caused the deposit of large quantities of silt and other debris in many channels.

In Santa Cruz County, Soquel Creek caused major flooding in the town of Soquel. Along the San Lorenzo River local flooding and evacuation

was reported at Felton Grove near Felton and Gold Gulch at the confluence of Zayante Creek.

In the Central Valley Area, high flows in a number of creeks in Tehama County, mainly Thomes, Mill, Cottonwood, and Deer Creeks, caused excessive erosion and destruction of levees. Erosion of natural stream channels, and deposition of sediment caused meandering of the stream channels within the flood plain.

Stony Creek broke through its levee in Colusa County during the height of the storm. The flood waters flowed across an open field, a county highway, and back into the creek channel in Glenn County. The flood waters cut a 100-foot wide channel in the topsoil along its path for a distance of about two miles.

Roads and highways were closed in Lake County due to the storm, and flooding caused damage to levees and flood control facilities on Middle Creek and Clover Creek Bypass within the Lake County Flood Control and Water Conservation District.

Flooding in Plumas County caused extensive damage in the vicinity of Chester, Portola, and Quincy, and damaged the water supply system of the town of Johnsville. Flood waters deposited large amounts of sand, gravel, and debris in the channels of Johnson Creek and the North Fork of the Feather River which so restricted the channels as to cause extensive flooding of private and public property in the Chester area.

The Yuba and American River Basins caught the brunt of this storm. Damage to roads and highways was extensive, and numerous communities and resorts were flooded causing widespread damage. The storm runoff from the Sierra slopes, which produces rivers with the highest fall and shortest

reach of any in the world, brought down tremendous quantities of debris resulting in damage to roads, highways, public and private property, and to numerous stream gaging stations. Debris choked Folsom Lake with logs and brush dislodged by the fast rising tributaries. The debris trapped in the lake cost $50,000 to be removed.

Flooding damaged the water supply and distribution system of the Washington County Water District to the extent that it was completely out of operation for about three months.

Daguerre Point Dam, property of the California Debris Commission, located on the Yuba River approximately nine miles upstream from Marysville was severely damaged. The function of the dam is to remove debris from the Yuba River so that the Sacramento River Flood Control Project channels are not effected by this material.

Construction is now under way to repair the dam. The total cost of repairs will be approximately $1,350,000 of which the State will pay 50 percent and the U. S. Federal Government will make up the other half.

The majority of damage to the Sacramento River Flood Control Project consisted of erosion of levees and banks sloughing off into the channels. Several boils developed and were promptly controlled. One instance of the more serious caving bank-type of damage occurred on the left bank Feather River located about 2 1/2 miles downstream from Nicolaus in Reclamation District No. 1001. The district forces placed canvas over the damaged reach which kept the erosion from worsening. Another serious condition developed in Maintenance Area No. 10 on the right bank American River. The waterward slope of the levee eroded, leaving a vertical face of five feet for a

distance of 350 feet. The department's maintenance personnel placed canvas and sandbags on this caved portion of the levee.

In the Sacramento River Delta, Little Holland Tract went under on the evening of February 1; Prospect Island overflowed about midnight on February 1; and Liberty Island flooded in the early morning of February 2.

In the northern portion of the Lahontan area the damages along the main rivers were found to be minimal, generally speaking, as compared to the problem created by the smaller creeks, which left normal channels and spread out over considerable areas.

Cold Stream and Weber Creek overflowed their banks and flooded the town of Sierraville causing considerable damage to State Highway No. 89 and to private property.

In the Donner Lake area there was considerable flooding at the northwest corner of Donner Lake caused by water originating in Negro Canyon. Sheet flooding deposited considerable silt and debris.

The main water supply line crossing over the Truckee River was washed out leaving a major portion of the town of Truckee without fire protection or domestic water supply.

In Alpine County along the West Fork Carson River between Woodfords and Paynesville, floods caused damage to diversion facilities which supply irrigation and domestic water.

In Antelope Valley, Slinkard and Rodreques Creeks blocked State Sign Route No. 395 and covered agricultural lands with silt. The greatest damages were at the town of Walker. Mill and Little Lost Canyon Creeks spread out through the portion of town above the state highway and then followed the highway northward to join the river.

Sheet flooding, which deposited silt, was widespread throughout the town of Bridgeport in Mono County. The flood water was largely runoff from the Bridgeport Meadows.

In Los Angeles and Orange Counties, high waves during the storm of February 1963 caused damage along the coast line. Public facilities in Redondo Beach King Harbor received the most severe damage in this area. High waves coupled with intense rainfall, caused breaches in revetted rock slopes, undercutting of concrete quay walls, and deposition of debris on the city-owned harbor facilities.

LEGEND

(a) USGS - United States Geological Survey
USBR - United States Bureau of Reclamation
DWR - Department of Water Resources
PGE - Pacific Gas and Electric Company
b - Site and datum then in use
c - Affected by storage and/or diversion
d - Discharge over weir
e - Estimated
f - Includes flow through powerhouse
g - Includes flow bypassing station
h - From flood marks
k - From graph based on observer's readings
l - Crest stage gage
r - DWR radio and telephone telemark log
s - Discharge not determined; affected by backwater from Tulloch Reservoir
t - Discharge to be determined later
* - Incomplete record
** - Maximum of Record
